

## The Physics of Power

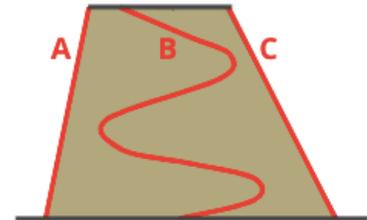

### Lesson Notes

#### Learning Outcomes

- How are power and work different than one another?
- How do you analyze physical situations to determine the power delivered by an object?

#### Constrasting Work and Power

- Work pertains to a force causing a displacement in order to change the energy of a system.
- Power: how fast the work gets done. It has a time component.
- To illustrate: Consider three paths - A, B and C - leading from the base of a hill to the summit. Each has a different angle and requires a different time. Which requires the most work? ... the most power?

Same work for each.

Most power: A

Least power: B

#### Defining Power

**Power** is the rate at which work is done.

$$\text{Power} = \text{Work/Time} \quad \text{or} \quad P = W / t$$

Two identical jobs require the same amount of work. But if one is to be done in less time, then it requires a greater power.

Unit: Watt (abbrev. W)      1 Watt = 1 Joule/second

#### Power Ratings

Machines are made to do work upon objects. Most machines are given a **power rating** to describe how fast they do the work. Power ratings are often given in the unit or **horsepower** (abbrev. **hp**).

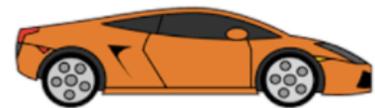

$$1 \text{ hp} = 746 \text{ Watt}$$

Car A: 150 hp Engine

Goes 0 mi/hr to 60 mi/hr in 15 seconds.

Car B: 750 hp Engine

Goes 0 mi/hr to 60 mi/hr in 3 seconds.

#### Power-Force-Velocity Relationship

$$\text{Power} = \frac{\text{Work}}{\text{time}} = \frac{F \cdot d}{t} = F \cdot v$$

$$\text{Power} = \text{Force} \cdot \text{Velocity}$$

#### Remember

$$v = d / t$$

v = velocity

d = displacement

t = time

## Personal Power Lab

A common lab in a Physics course.

Run up a flight of stairs and determine your power rating.

Typical data and calculations are shown.

Lab #22:	Personal Power Lab
Purpose:	To determine my running power in ascending a flight of stairs.
Data:	mass = 82 kg height = 1.8 m time = 1.03 s
Calc'ns:	Force = $m \cdot g = (82 \text{ kg}) \cdot (9.8 \text{ N/kg}) = 803.6 \text{ N}$ Work = $F \cdot d \cdot \cos \theta = (803.6 \text{ N}) \cdot (1.8 \text{ m}) \cdot \cos 0^\circ$ Work = 1446.46 J Power = $W/t = (1446.46 \text{ J}) / (1.03 \text{ s})$ Power = 1400 W (1404.34... W) $\Rightarrow$ 1.9 hp

Show your solution to each of the following problems.

### Power Calculations - Example 1

When doing a chin-up, a 42-kg student lifts her body upward a distance of 0.25 m in 1.3 seconds. Determine the power delivered by the student's biceps.

### Power Calculations - Example 2

During a football workout, the line coach stands on a training sled (combined mass = 245 kg) as three linemen push the sled across the field ( $\mu=0.825$ ) at a constant speed of 1.60 m/s. Determine the combined power of the linemen.
